

# **Two-Step Position Detection for NIF Automatic Alignment**

**Presentation to  
LLNL CASIS Workshop  
Livermore, California**

**Abdul Awwal**

**Automatic Alignment & Imaging Team  
Integrated Computer Controls System  
National Ignition Facility (NIF)  
Lawrence Livermore National Laboratory**

**November 18-19, 2004**

UCRL-PRES-208084

The work was performed under the auspices of the U.S. Department of Energy National Nuclear Security Administration by the University of California Lawrence Livermore National Laboratory under Contract No. W-7405-ENG-48.

# Outline

---

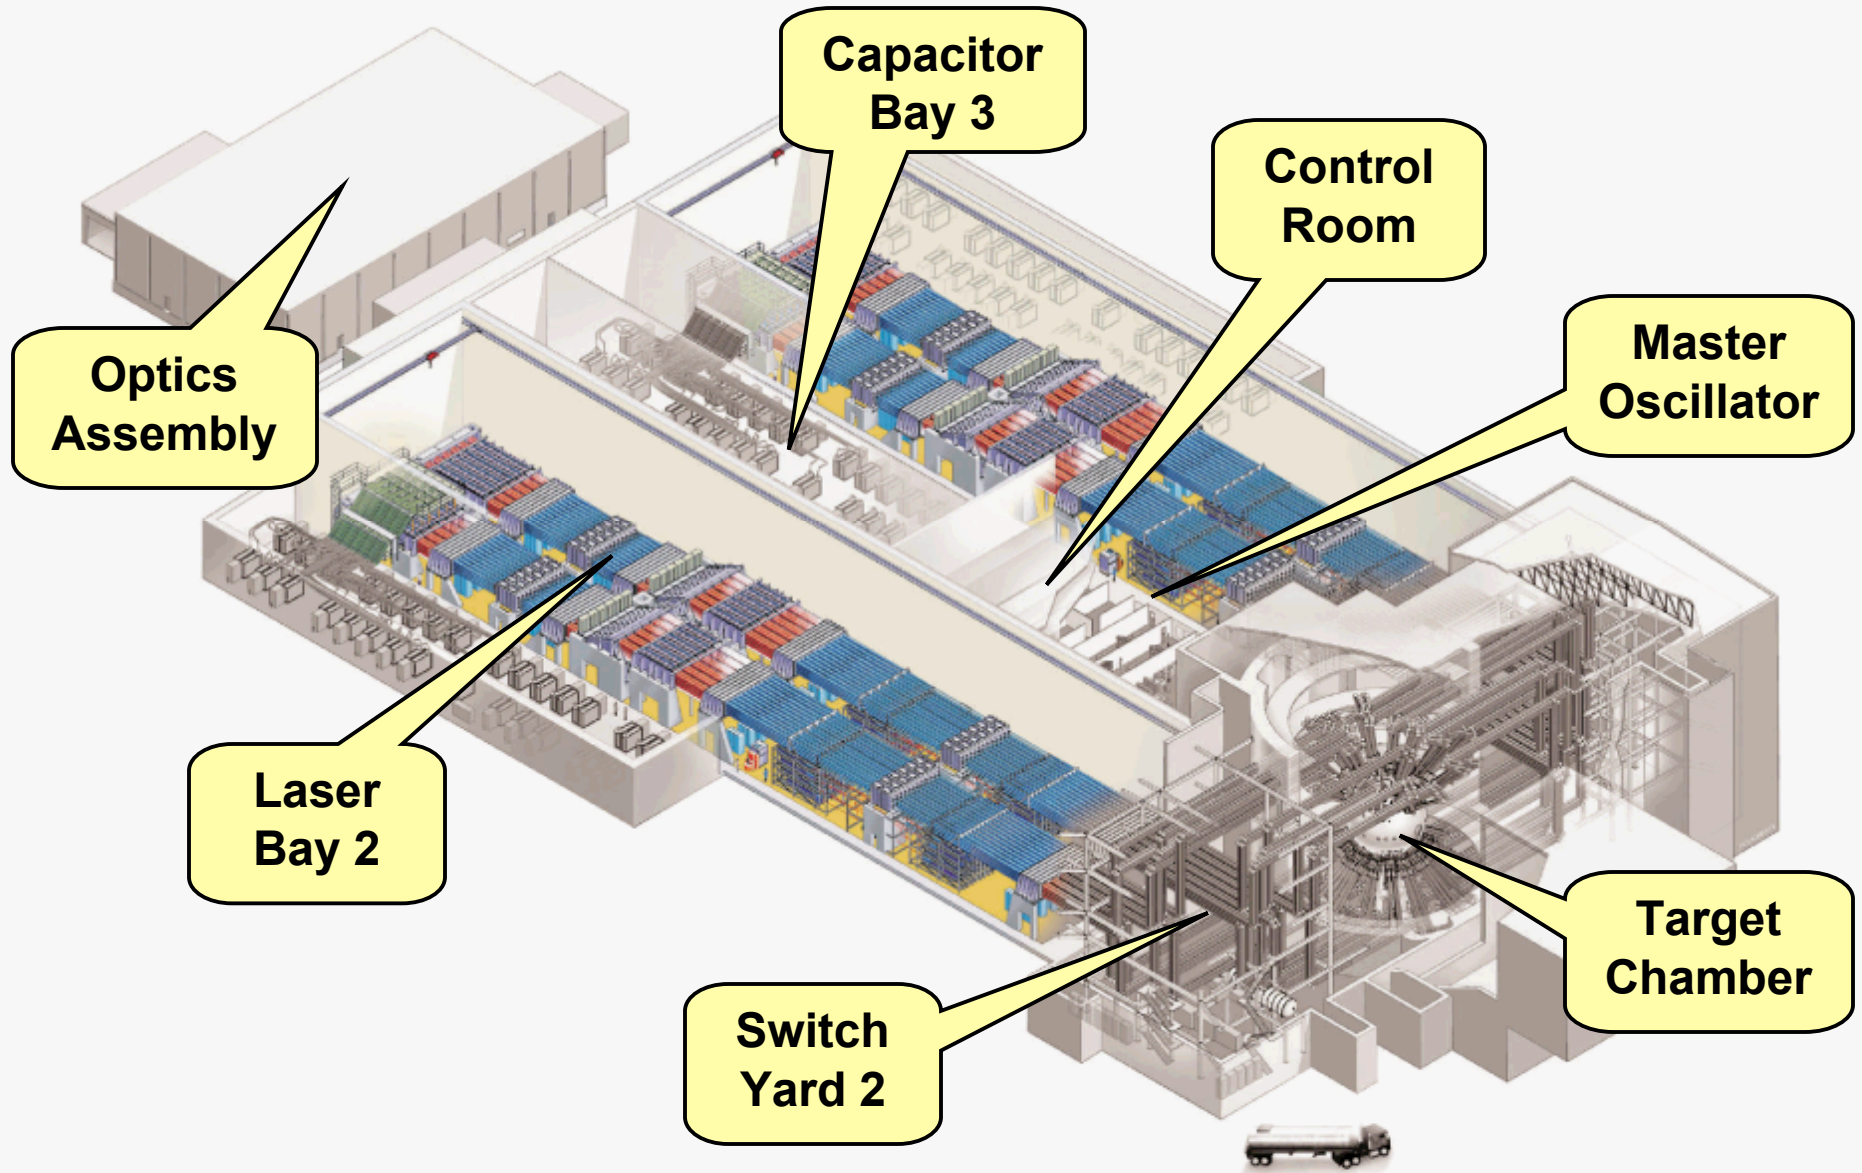

*The National Ignition Facility*

- **Introduction**
- **Problem Statement**
- **Background**
- **Two step algorithm examples: simple to complex**
- **Results**
- **Challenges**

# National Ignition Facility

# Automatic alignments need automated detection of beam position and automatic mirror adjustments

- Automatic alignment uses video images of fiducials to find positions of laser beam

# **Problem: How do we detect positions when the fiducials vary in shape and size?**

---

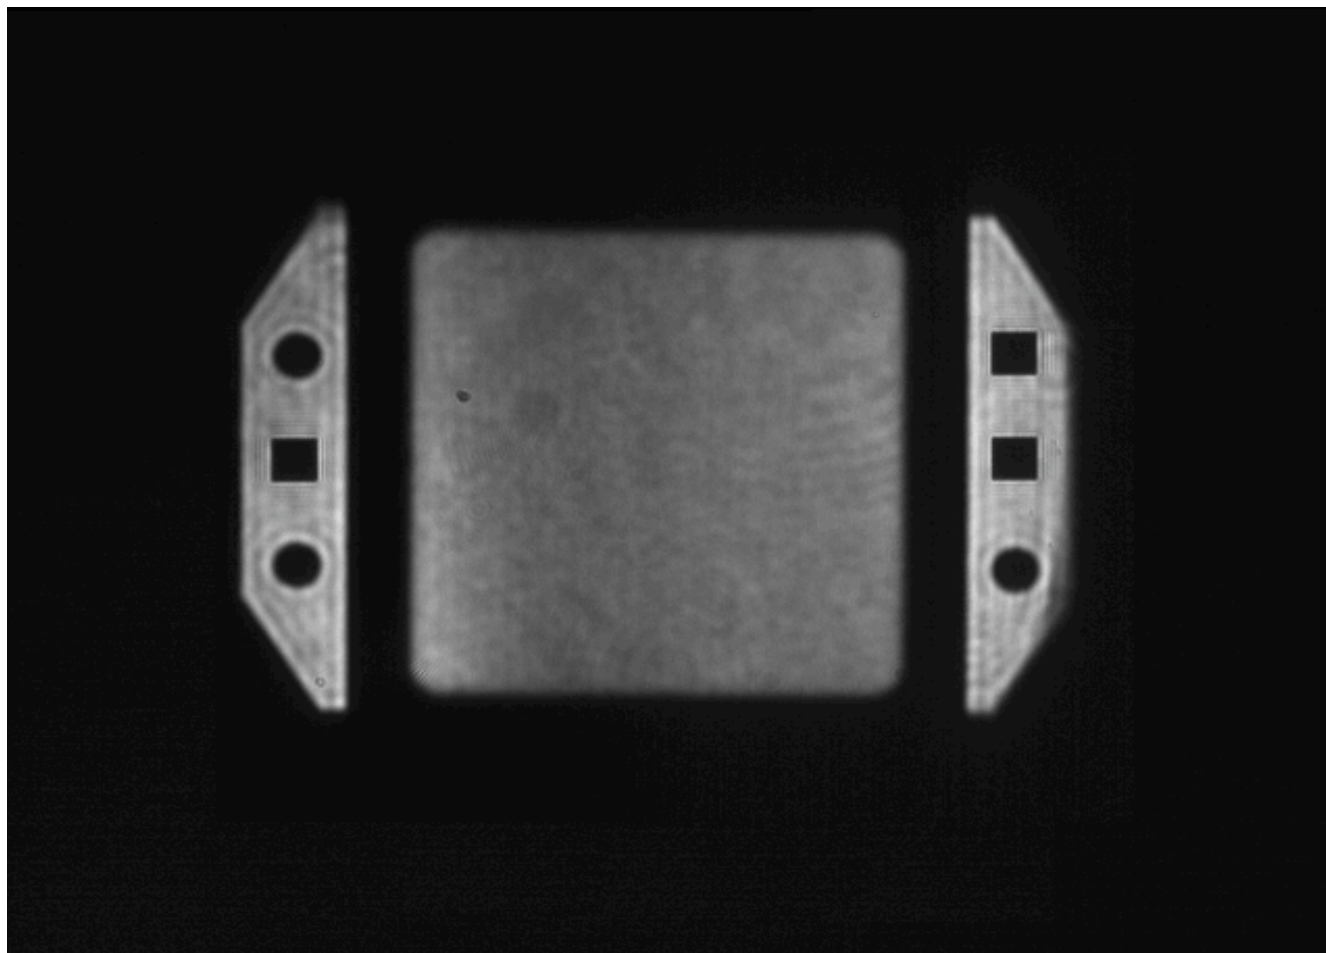

*The National Ignition Facility*

- **Automatic alignment needs to detect position of beam**
  - **Challenges**
    - **Beams with different markers**
    - **Same marker, but sizes vary due to defocus**
    - **Circles of different sizes**
    - **Variations relatively large**

# Alignment image contains circles and squares

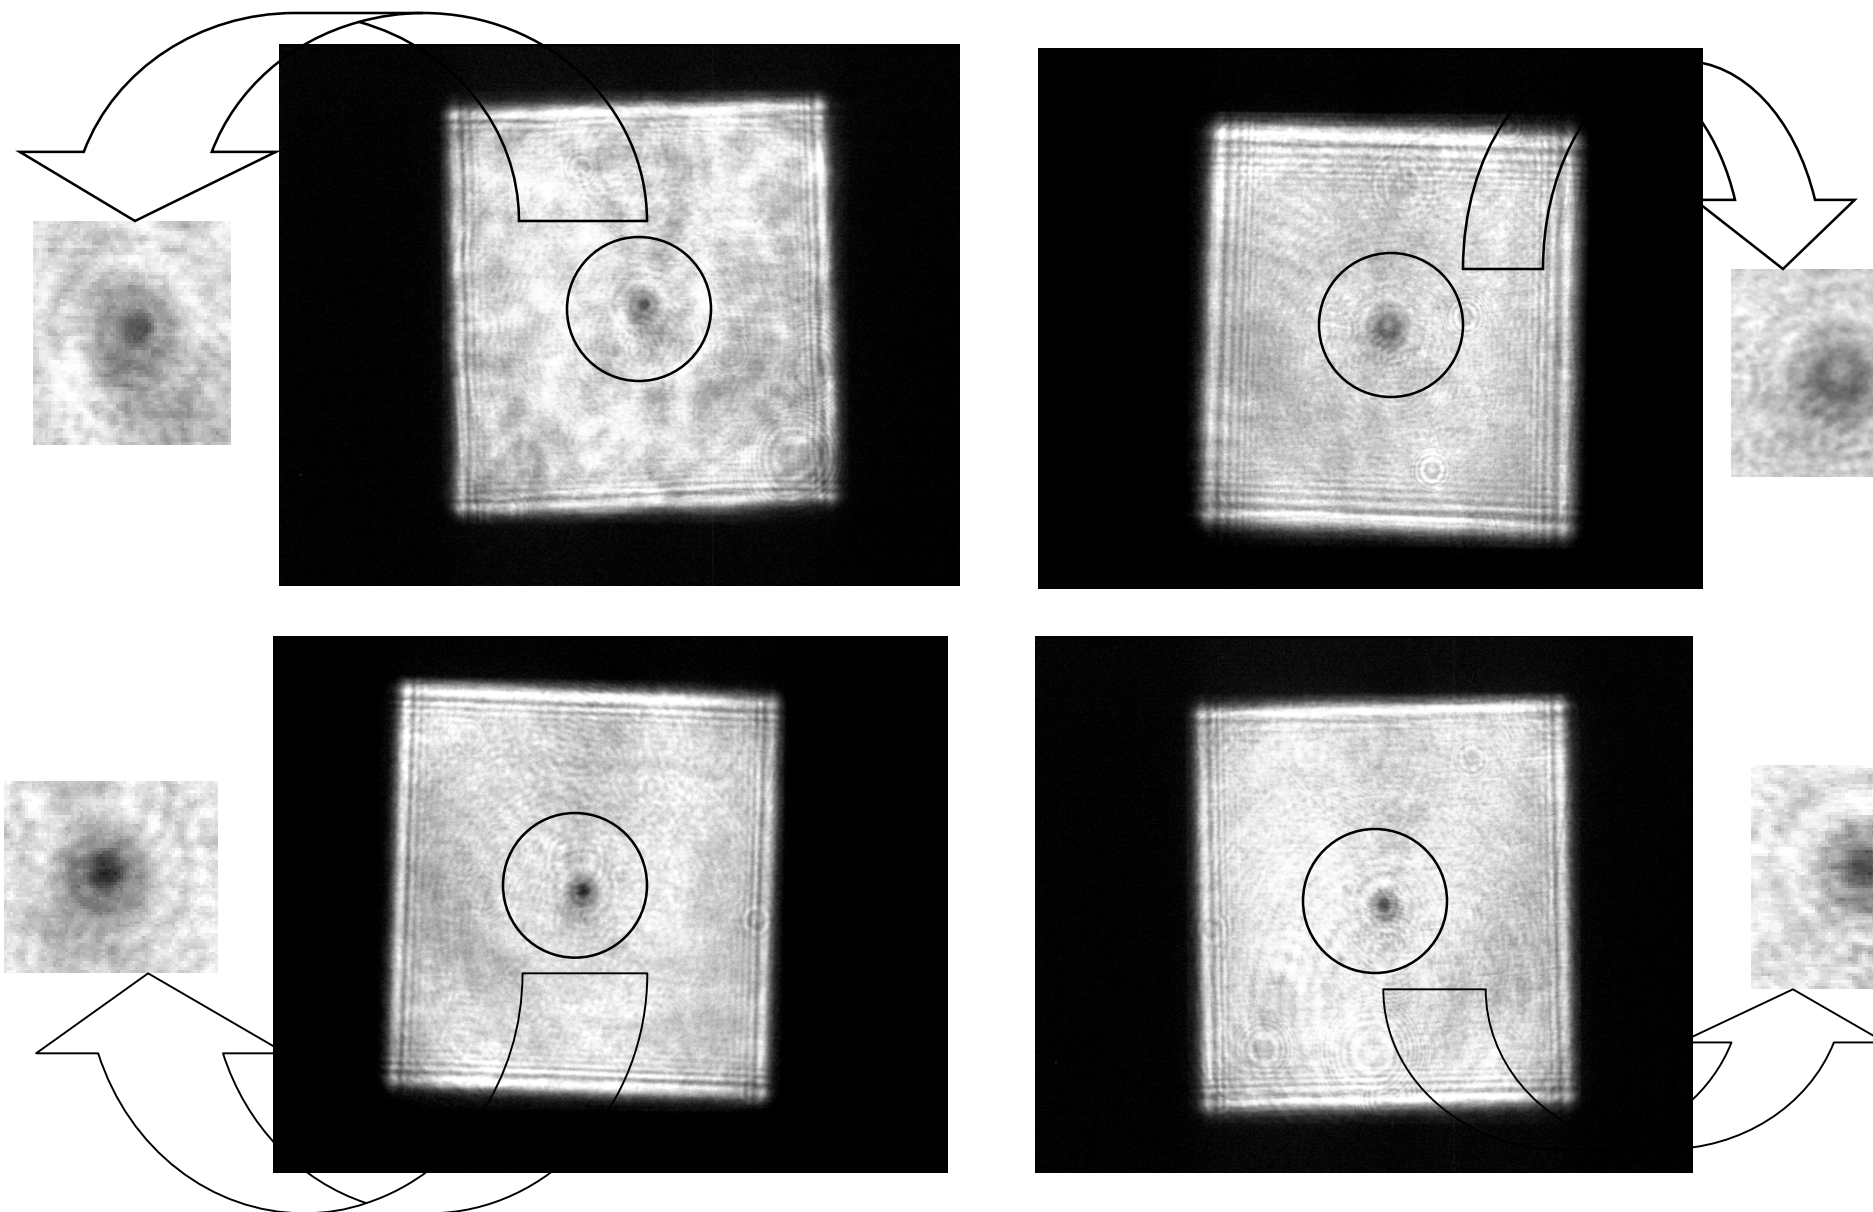

The National Ignition Facility

# Defocused spots exhibit wide variation in size and quality

The National Ignition Facility

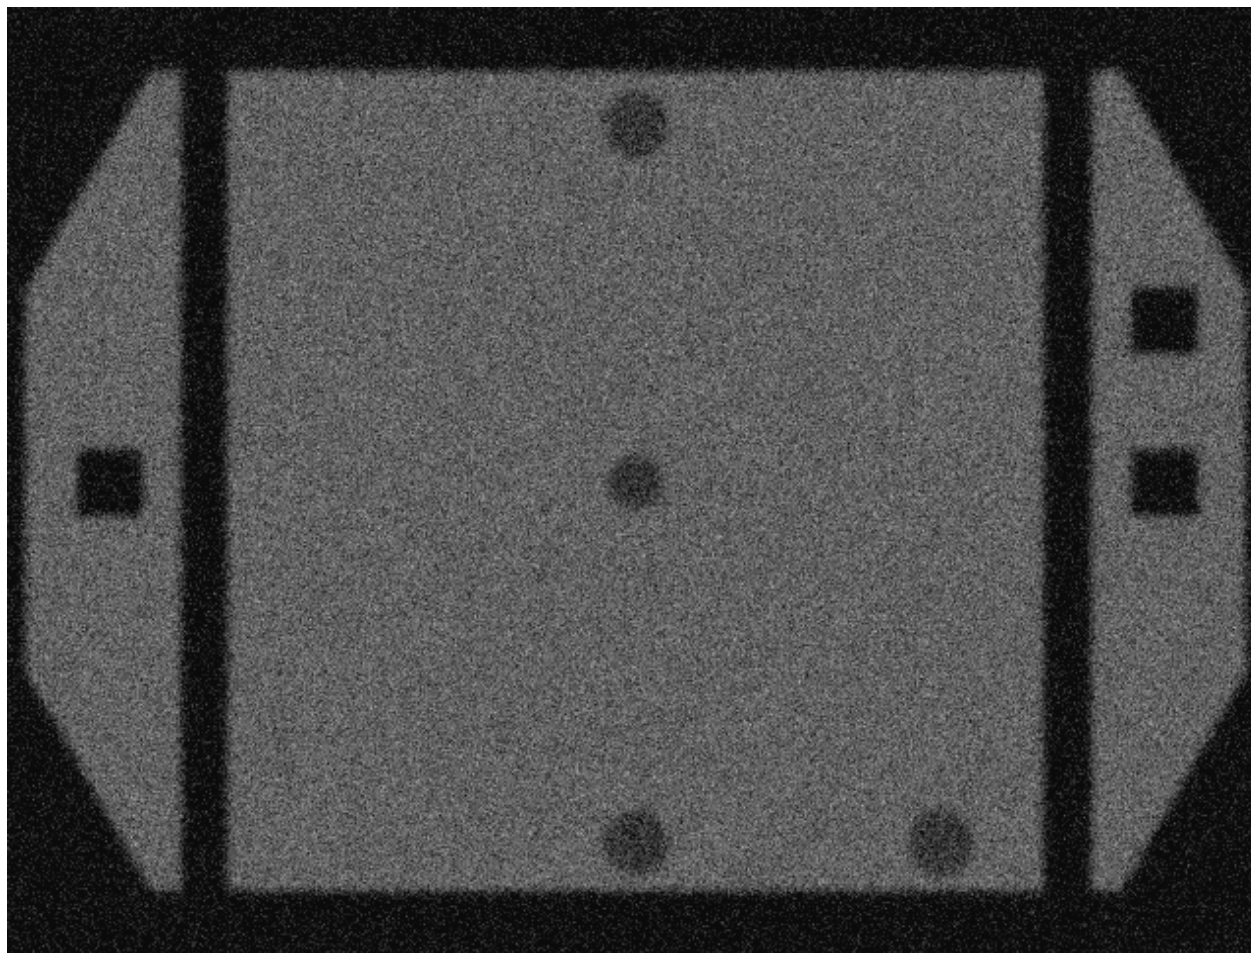

# Different markers identify different beams

---

The National Ignition Facility

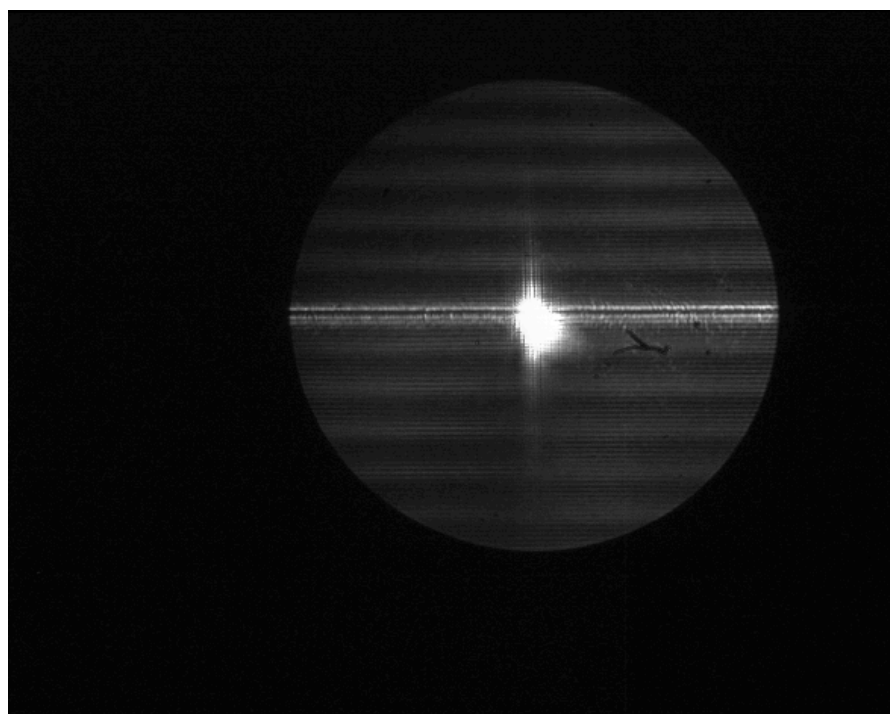

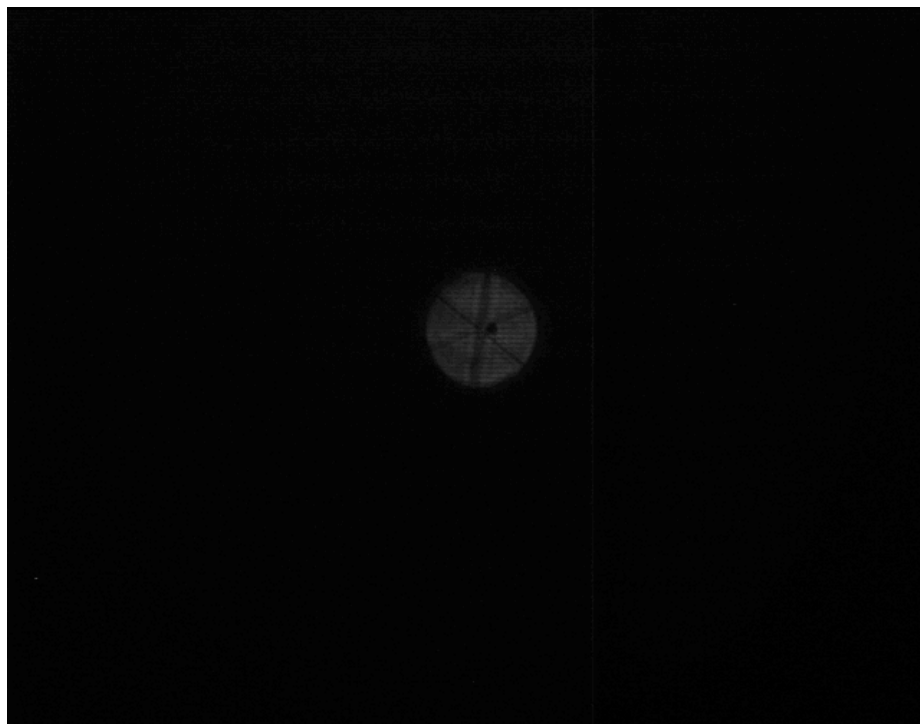

# Some alignment images vary from 35 pixels to 200 pixels

---

*The National Ignition Facility*

# Possible solutions

---

*The National Ignition Facility*

- Centroid
- Template

**How to choose the template?**

# Algorithm background

The National Ignition Facility

## CMF

$$H_{CMF}(U_x, U_y) = F^*(U_x, U_y) = |F(U_x, U_y)| \exp(-j \angle (U_x, U_y))$$

## POF

$$H_{POF}(U_x, U_y) = \exp(-j \angle (U_x, U_y))$$

## AMPOF

$$H_{AMPOF}(U_x, U_y) = \frac{aF^*(U_x, U_y)}{\left[ b + c|F(U_x, U_y)| + d|F(U_x, U_y)|^2 \right]^n}$$

**Position is obtained from cross and auto-correlation and the original template location**

---

The National Ignition Facility

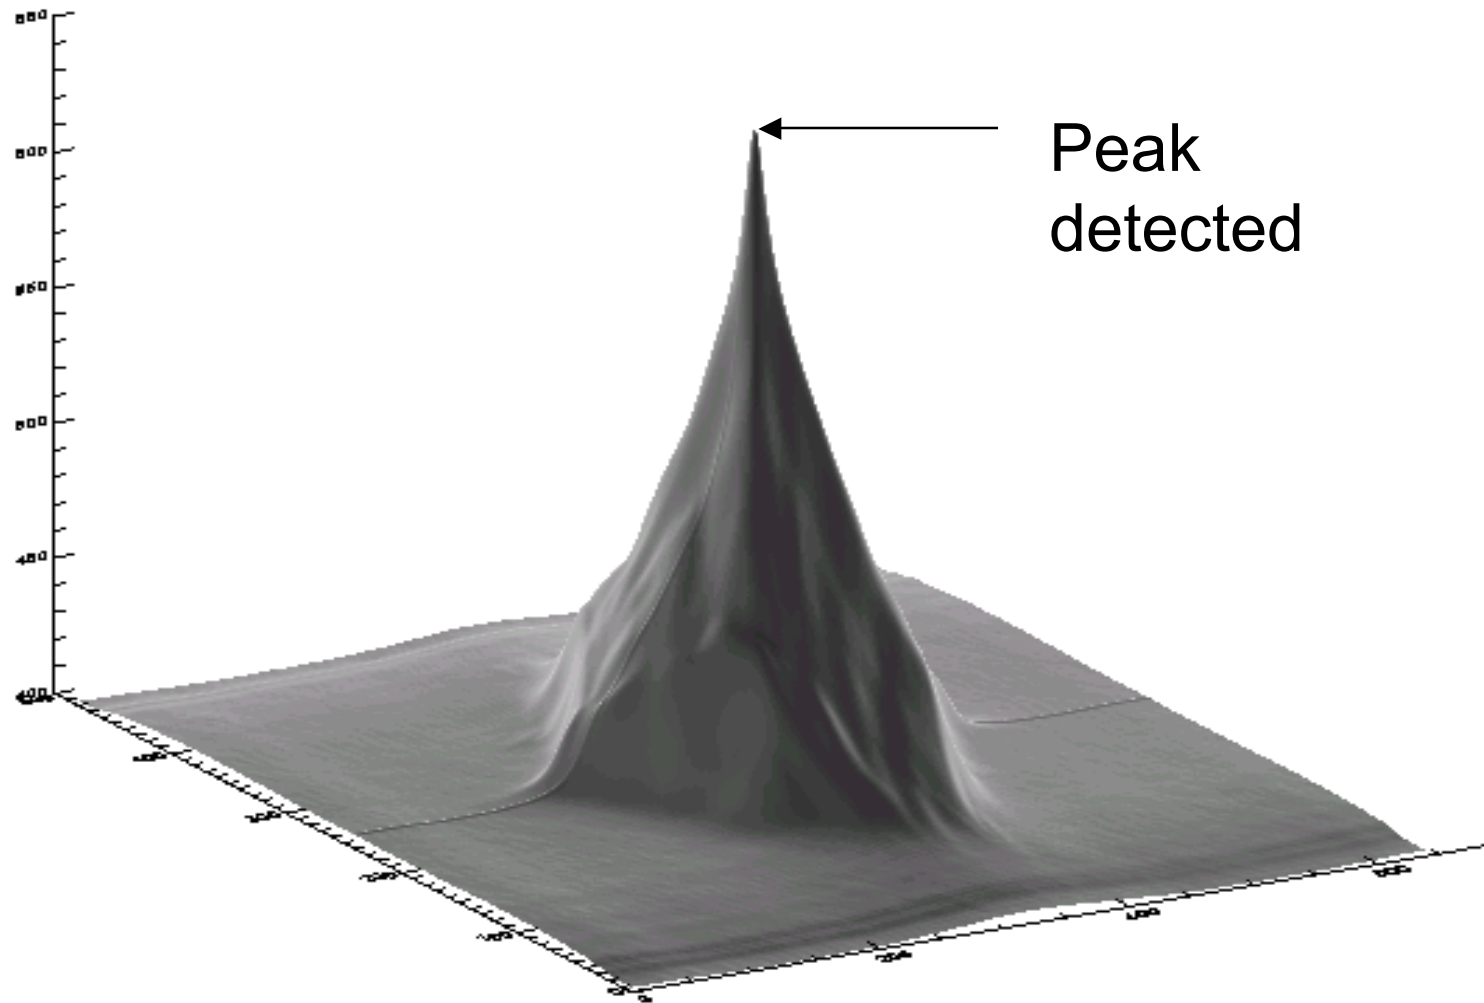

$$x_{pos} = x_{cross} \square x_{auto} + x_c$$

$$y_{pos} = y_{cross} \square y_{auto} + y_c$$

# CMF output shows cross-correlation location

The National Ignition Facility

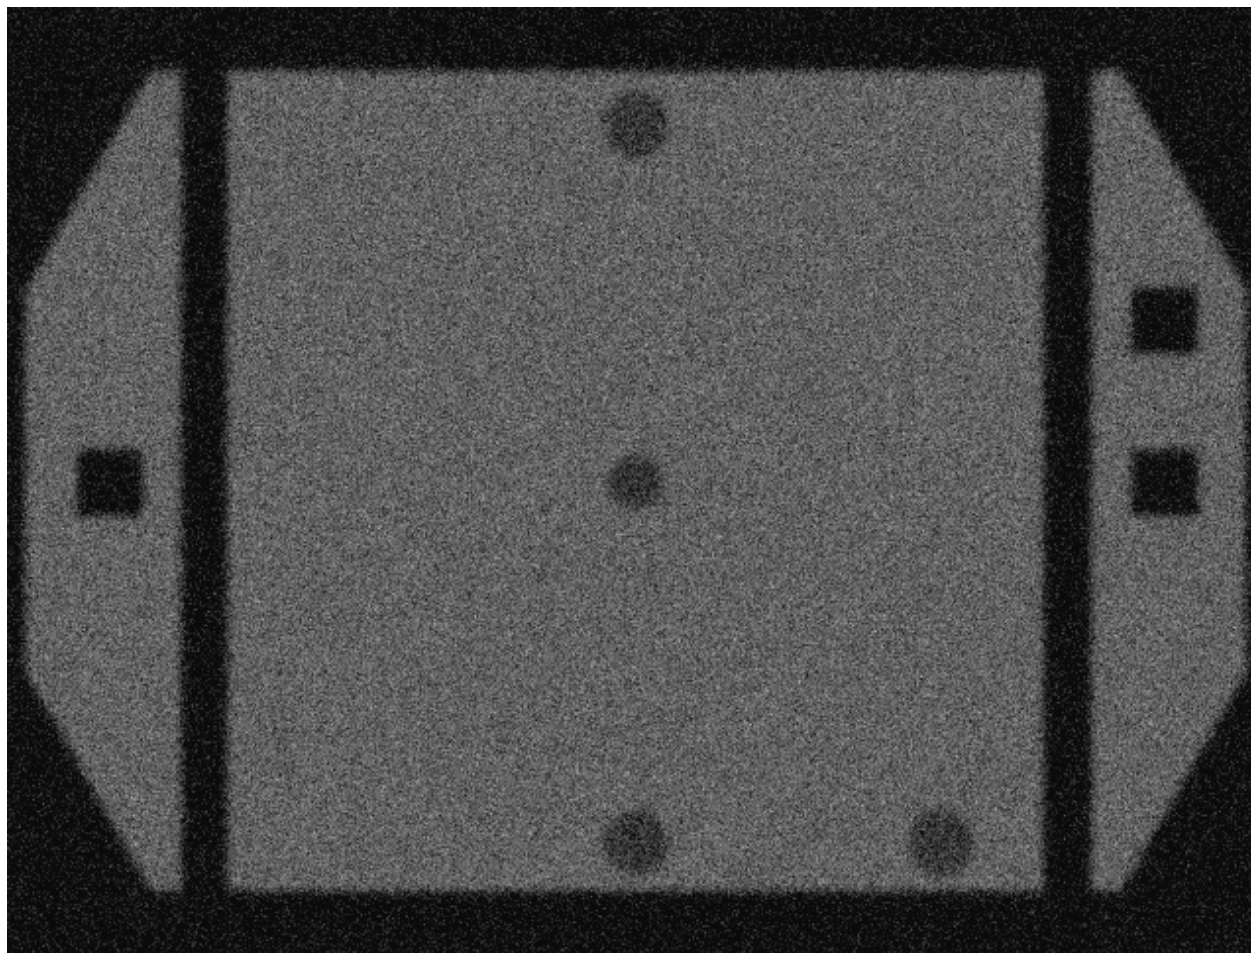

# Problem

---

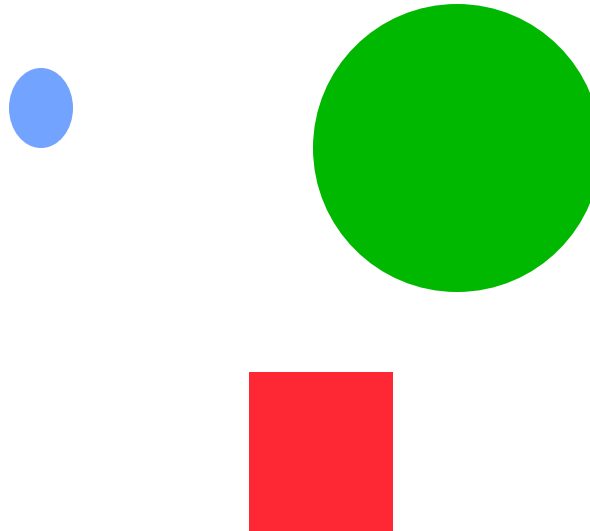

*The National Ignition Facility*

# Problem

---

- Two circles,  $r_1 < r < r_2$  and  $r_3 < r < r_4$
- Square,  $d_1 < d < d_2$

- Why ?
- By design
- Due to optics

# Two step approach

- Step 1: Search for right radius

- Segment based on blob size
  - Segment 1, less than 800
  - Segment 2, between 900 and 1100
  - Segment 3, between 1200 and 1400

- Change to square, repeat step 1

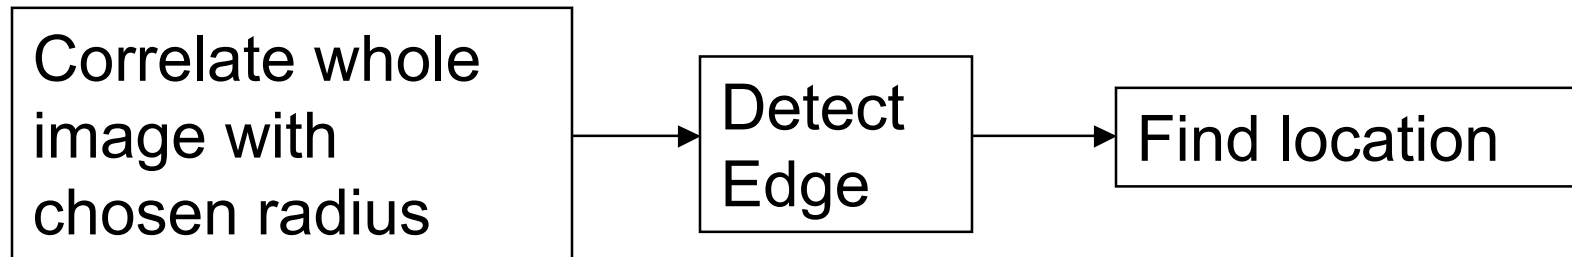

# Two step process

---

*The National Ignition Facility*

- **Step 2: Find the position**

- **Change to square, repeat step 2**

# **Segmentation is performed based on pixel size**

---

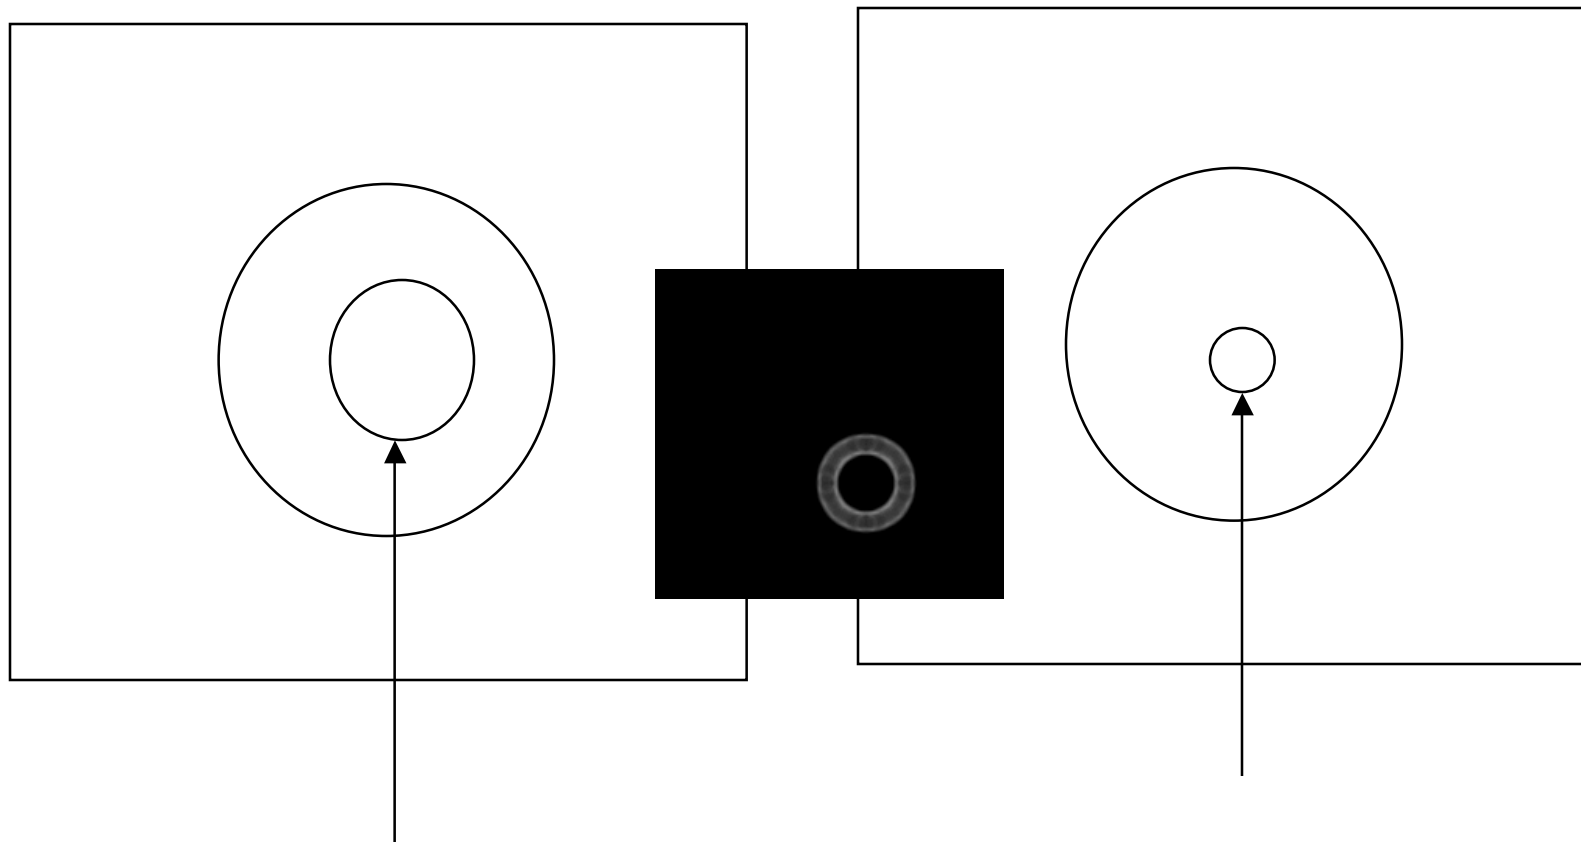

*The National Ignition Facility*

- **Feature sizes of interest (area in pixels)**  
**(1086, 1074, 1086, 836, 832, 836)**
- **Searching for squares (589.0, 158.5)**
- **Searching for circles at (52.0,158.0)**

# Movie of the circle match in the correlation plane shows correlation becomes a point at right radius

The National Ignition Facility

Correlation is also  
a circle

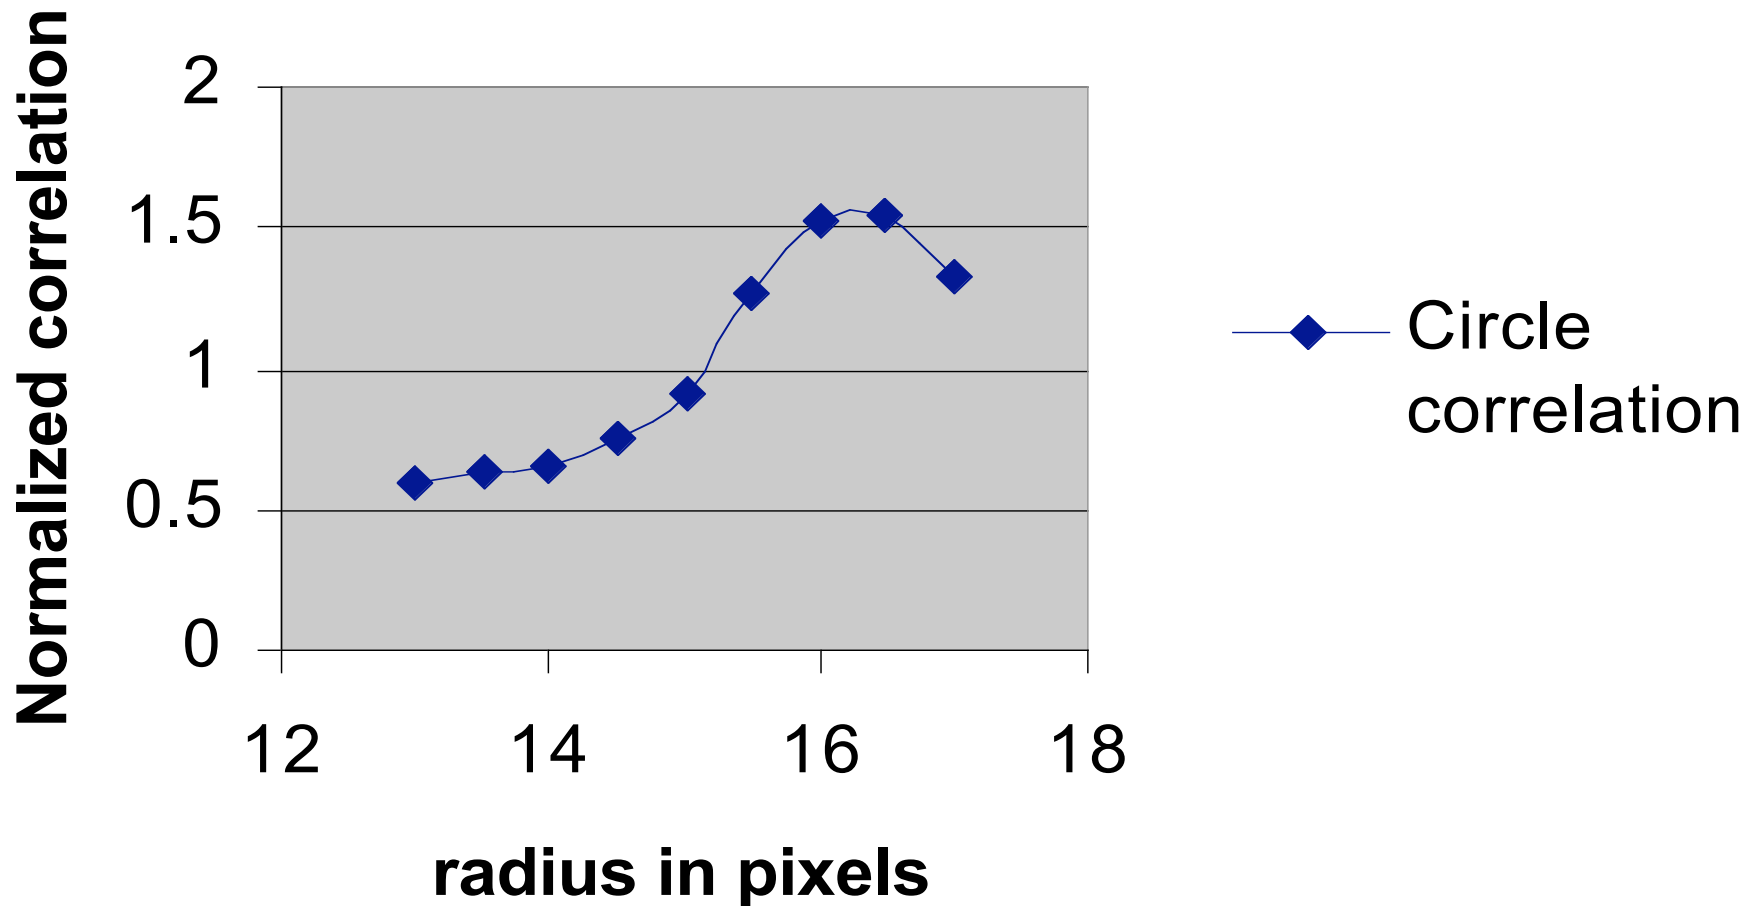

Circle becomes  
smaller as it nears  
the right radius

## Search selected 16.5 pixels for circle radius

The National Ignition Facility

### Correlation vs radius

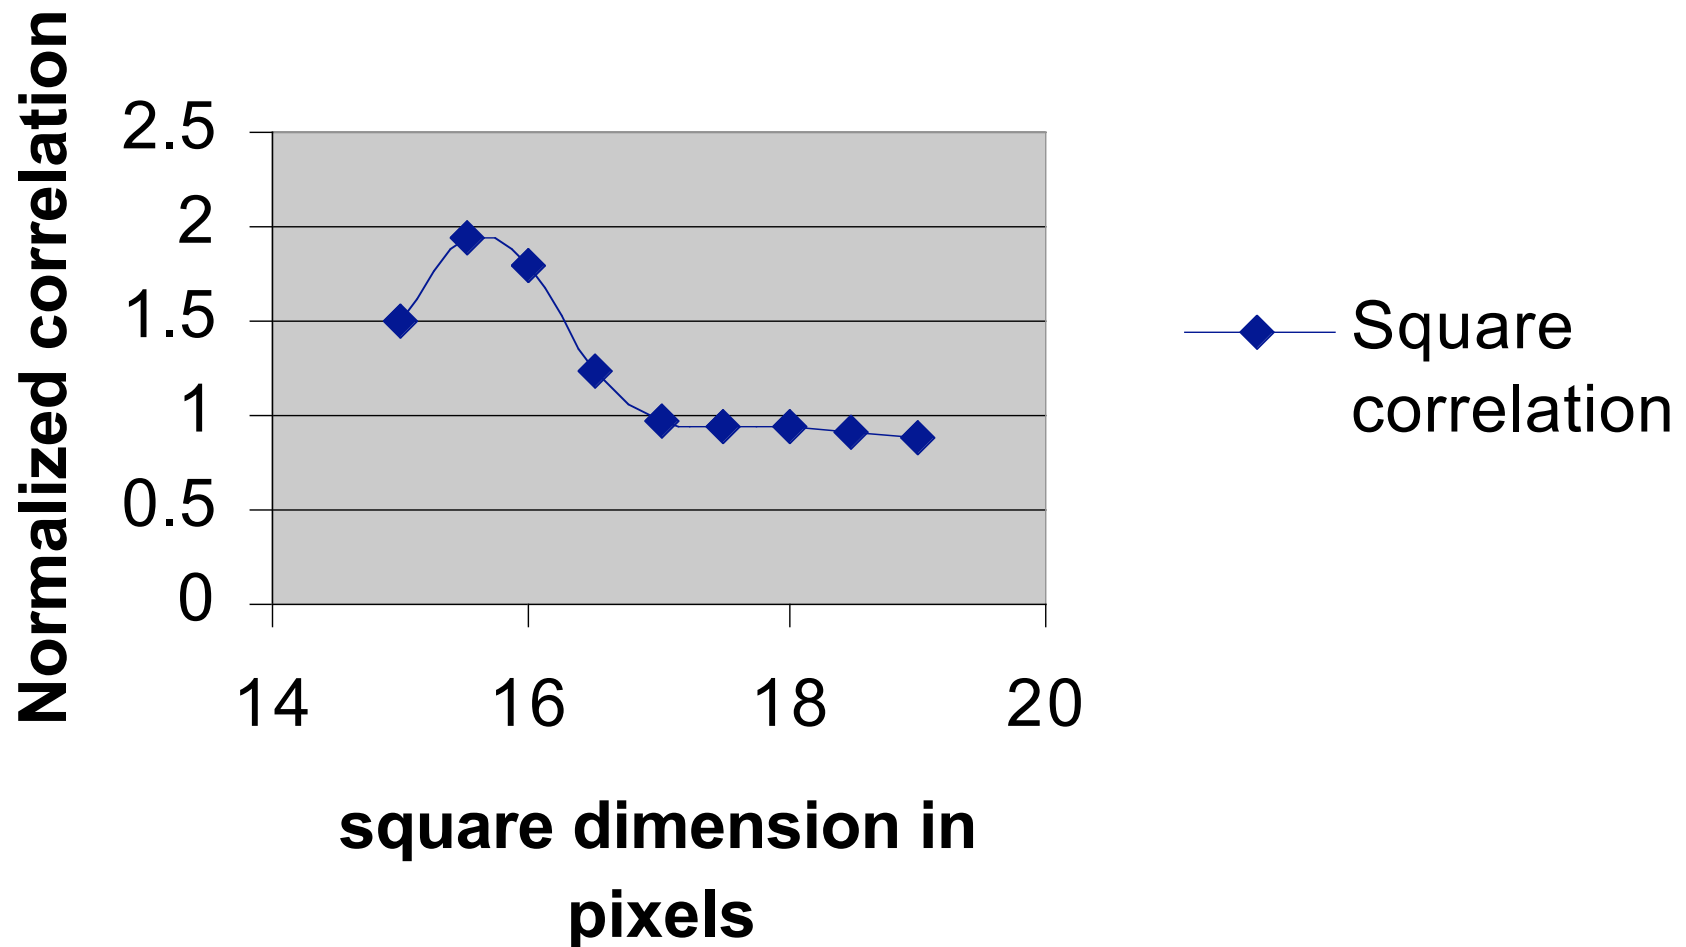

# Search selected square with dimension of 15.5 pixels

The National Ignition Facility

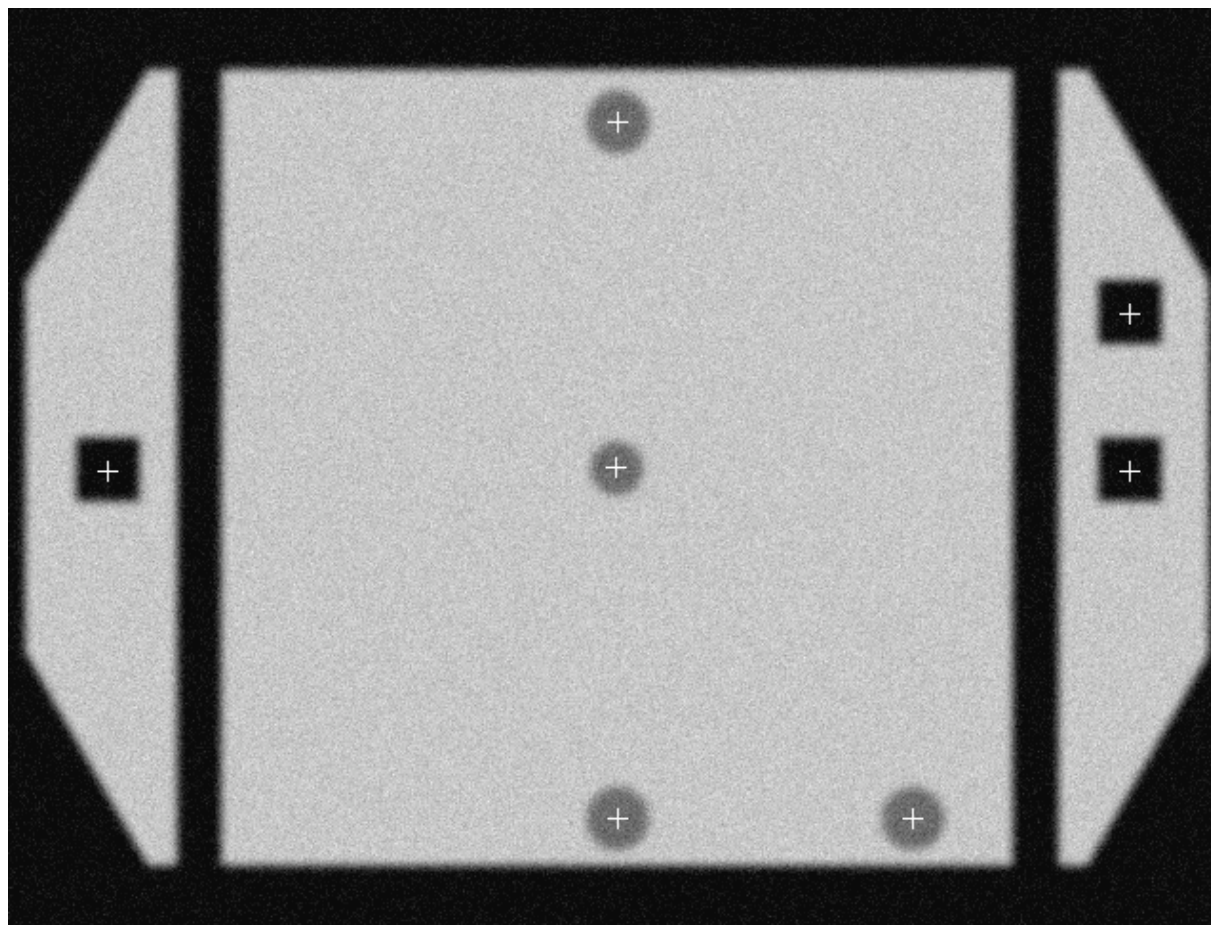

## Correlation vs side

# Circles of two sizes and squares of a single size detected (after 3 searches and 3 correlations)

The National Ignition Facility

## Example 2

---

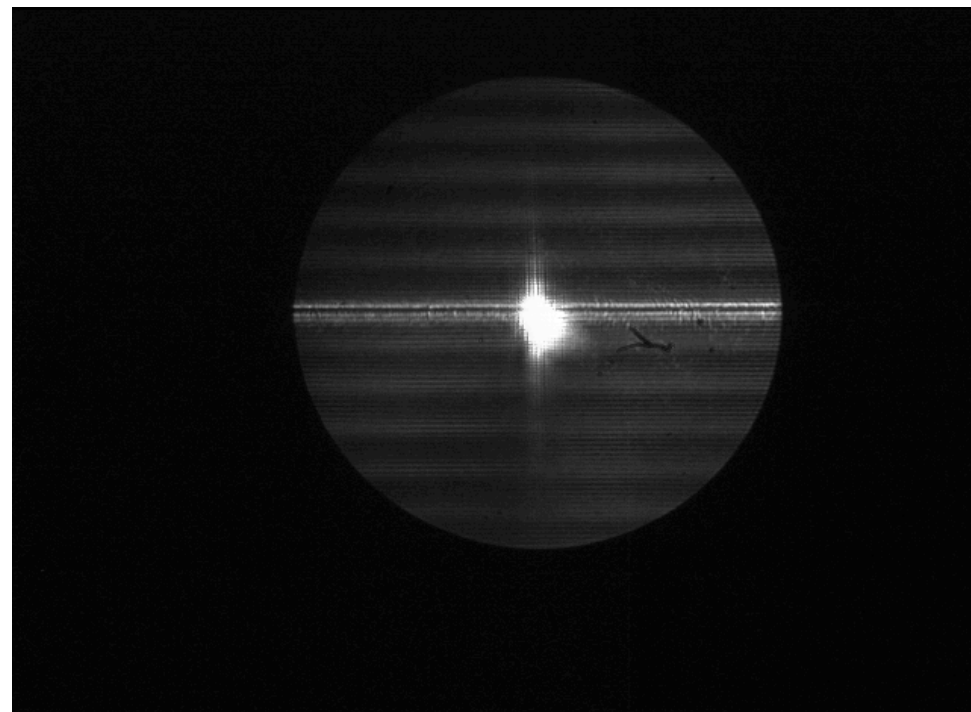

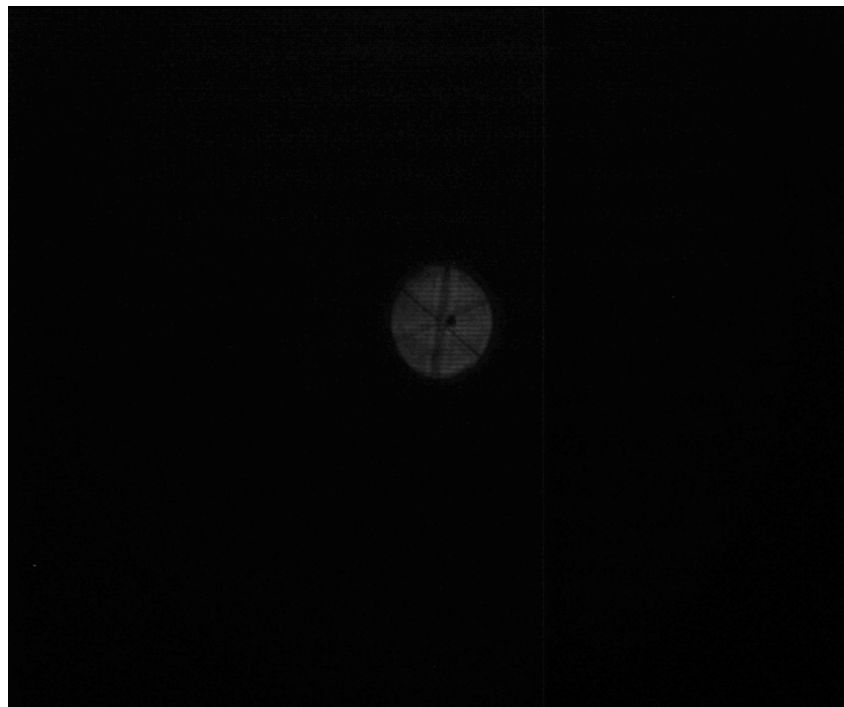

*The National Ignition Facility*

- 5 circles,  $r_1 < r < r_2$ 
  - Where  $r_1 = 35$  and  $r_2 = 260$

**Pinhole images could vary from 35 pixels to 200 pixels (radius)**

*The National Ignition Facility*

## Solution to complex problem: Example 2

The National Ignition Facility

- **Successive approximation**

Centroid

Section the image  
at centroid

Estimate  $r_1 < r < r_2$

- **Search by matching**

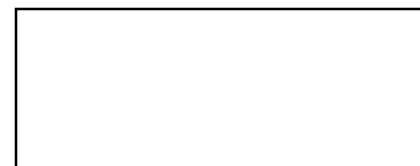

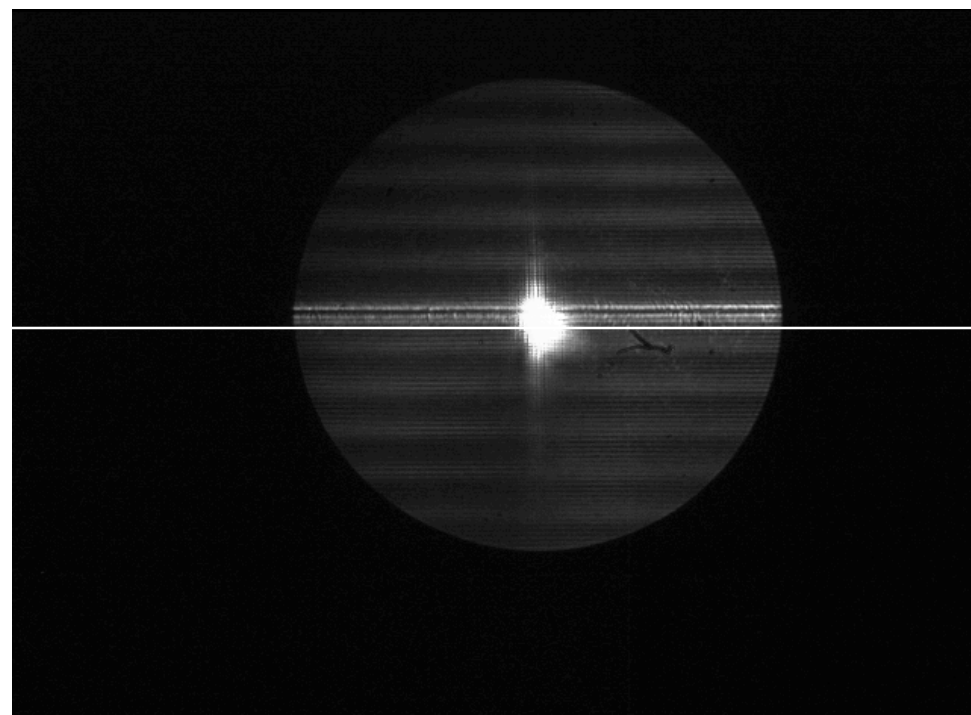

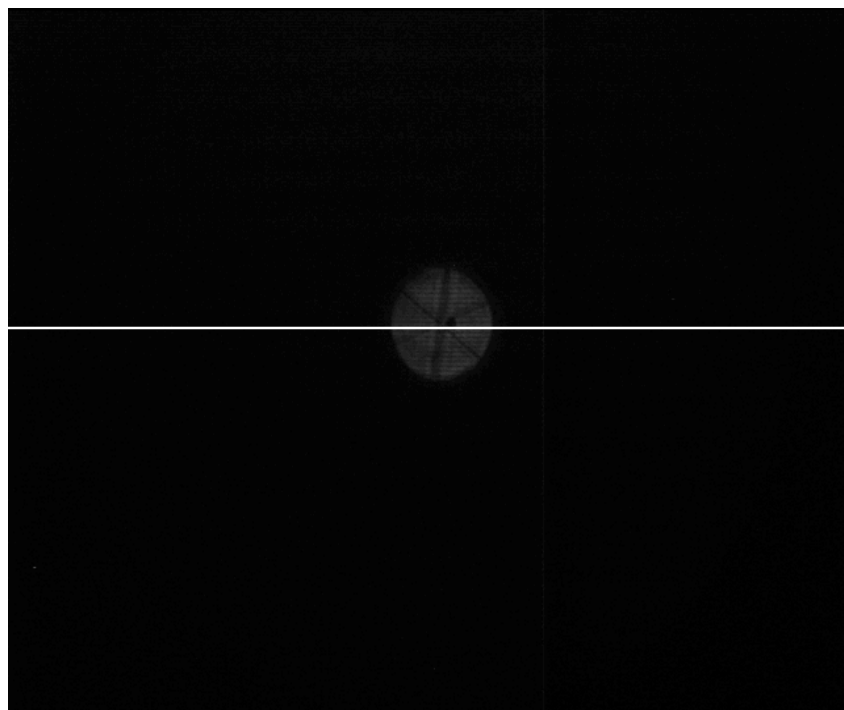

Correlate whole  
edge image with  
radius range

Find location

**Cross-section of images could provide an initial estimate of the radius such as 37 and 204 pixels**

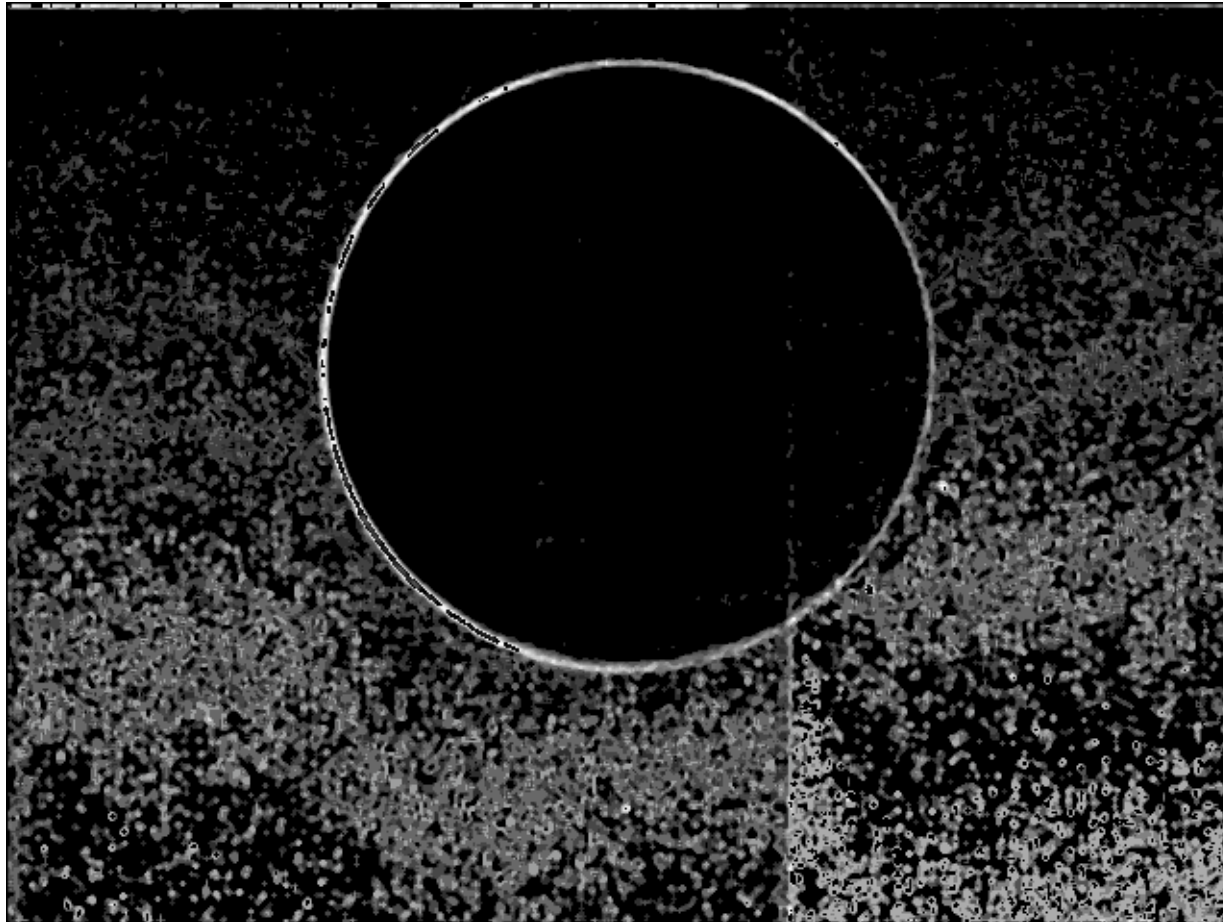

*The National Ignition Facility*

# Edge detected image

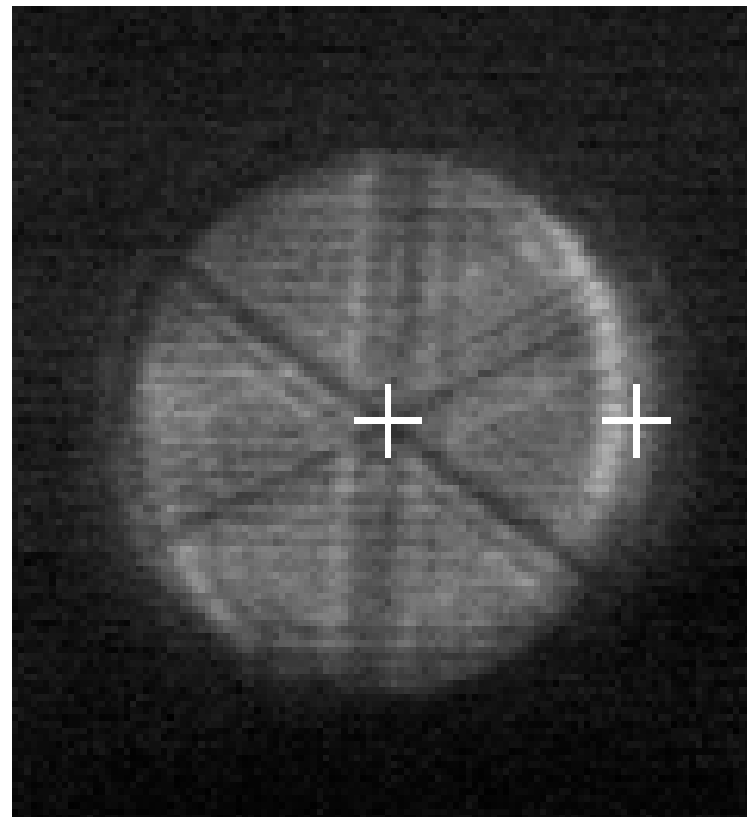

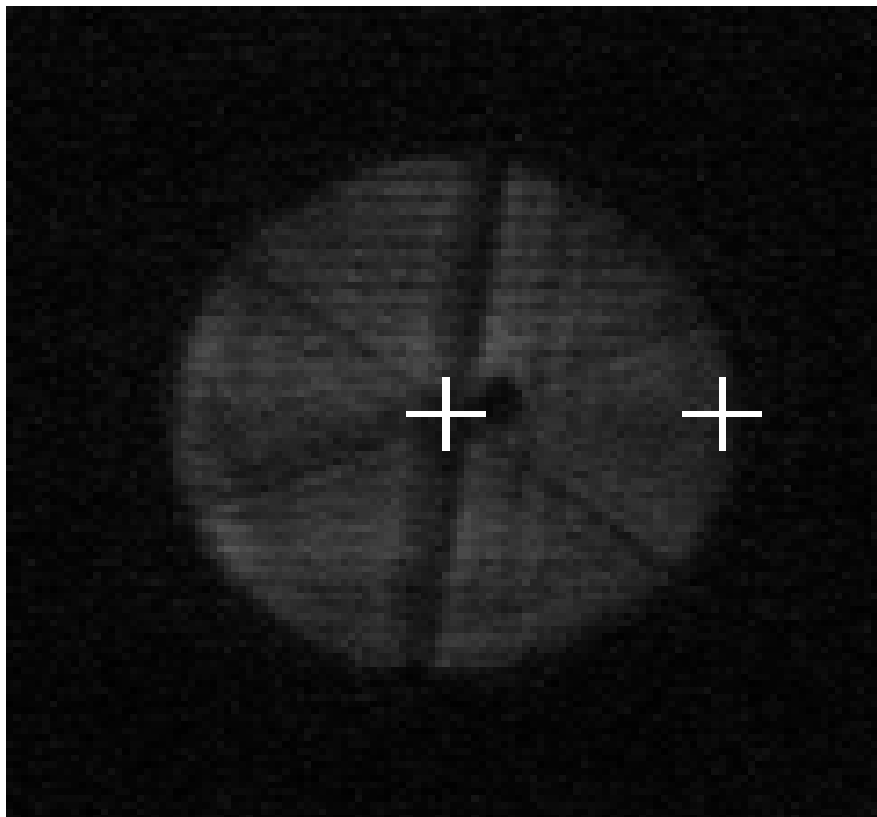

---

# Two typical final results show the edge and center of the circular images

*The National Ignition Facility*

# Refined algorithm

The National Ignition Facility

- Successive approximation

Segment the image find ROI

Measure the  
pedestal

Estimate  $r_1 < r < r_2$

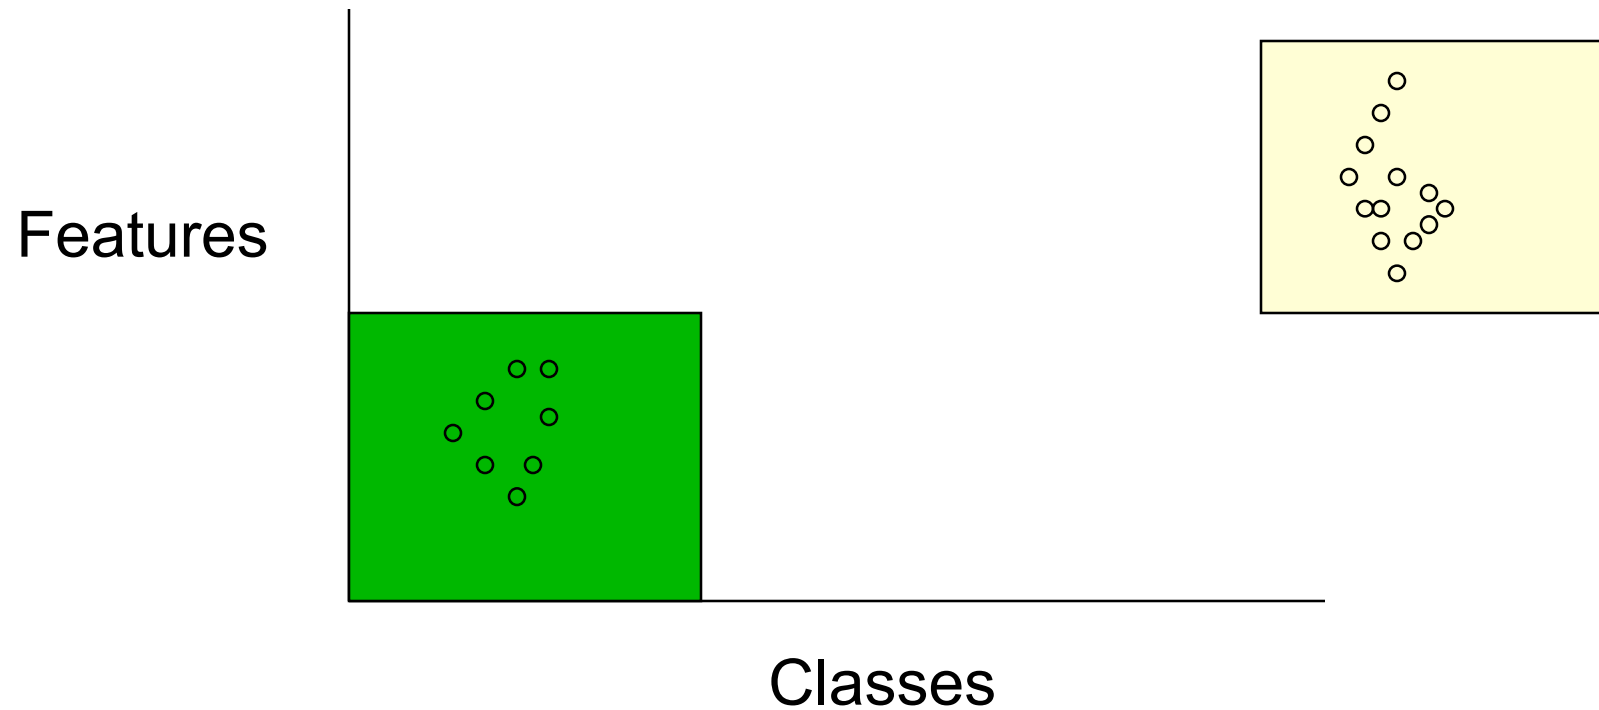

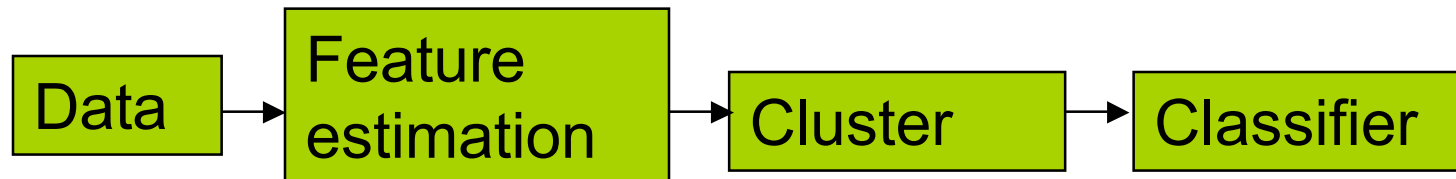

- Search by matching

Correlate  
segmented image  
with range of  
radius

Find location

More detailed in paper no. 5556-30

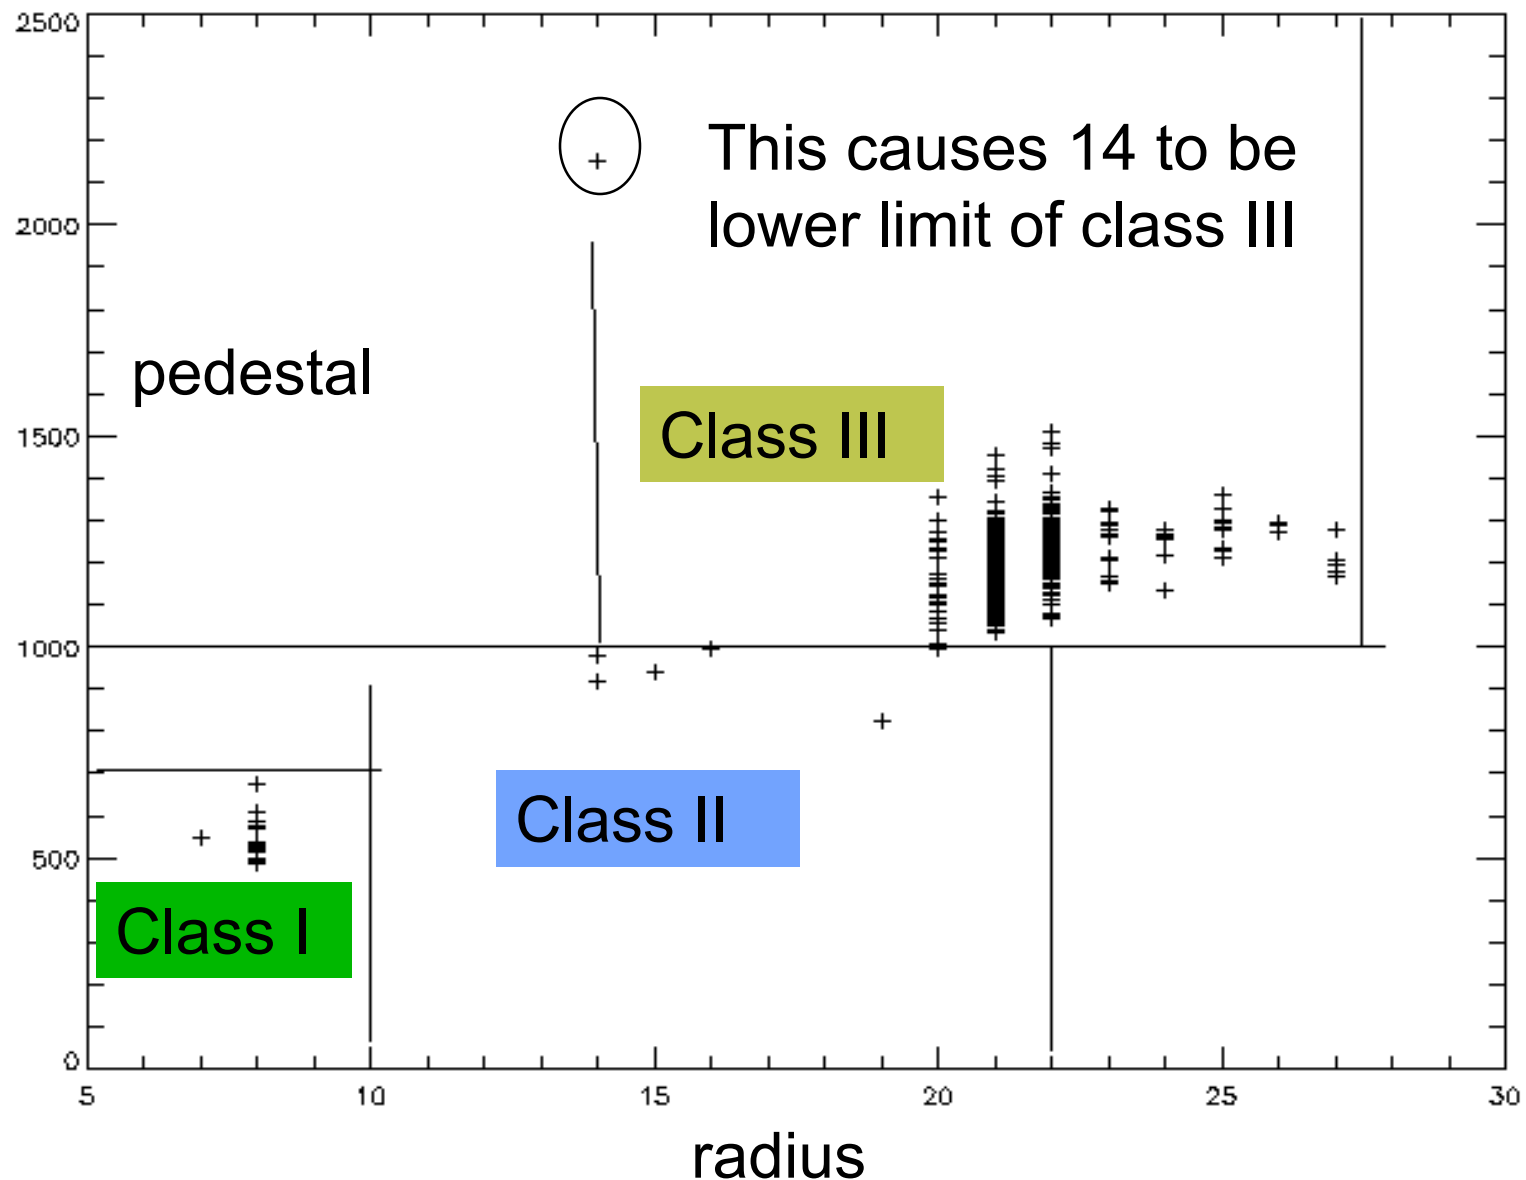

# Box classifier

# Search space shows 3 classes, range is chosen to bound the class- box classifier

The National Ignition Facility

## Box classifier

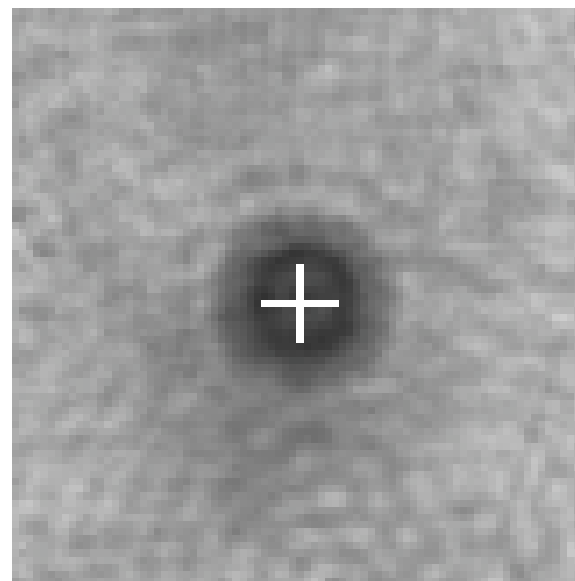

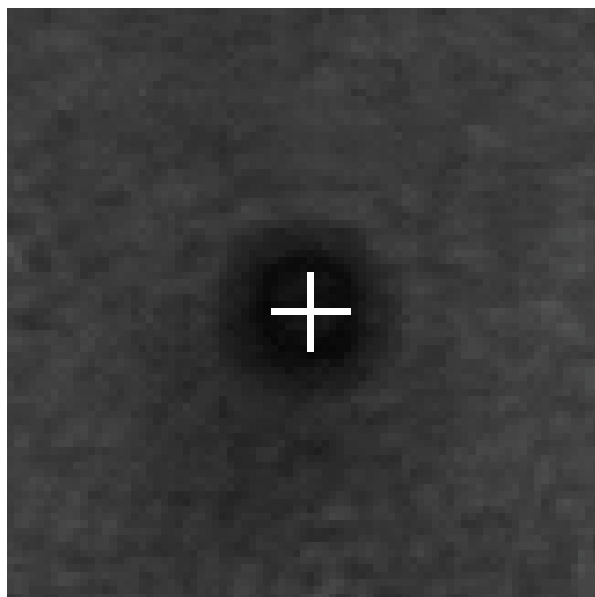

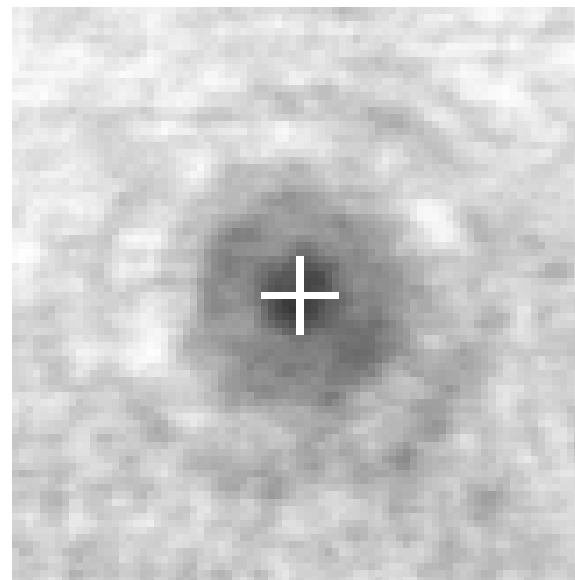

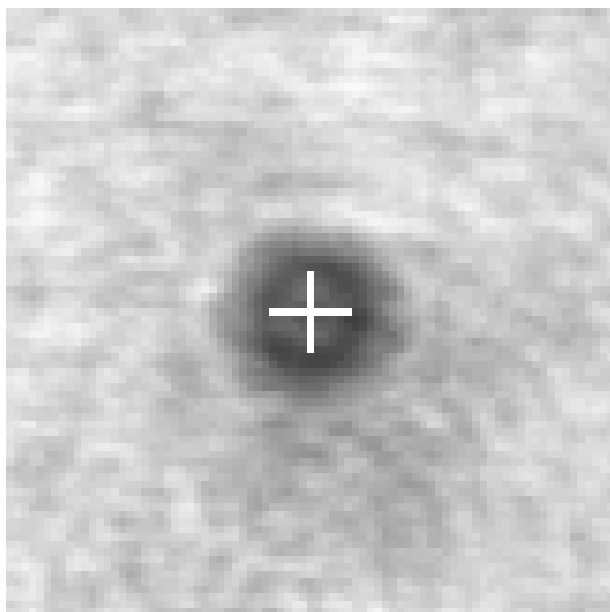

The National Ignition Facility

Measure the  
pedestal area

Estimate  $r_1 < r < r_2$

```
if (pedestal lt 700) then
    minRad=5
    maxRad=10
elseif (pedestal lt 1000) then
    minRad=11;
    maxRad=22
else
    minRad=14 ;
    maxRad=27
end
```

# Detection of four defocused spots

# Challenges

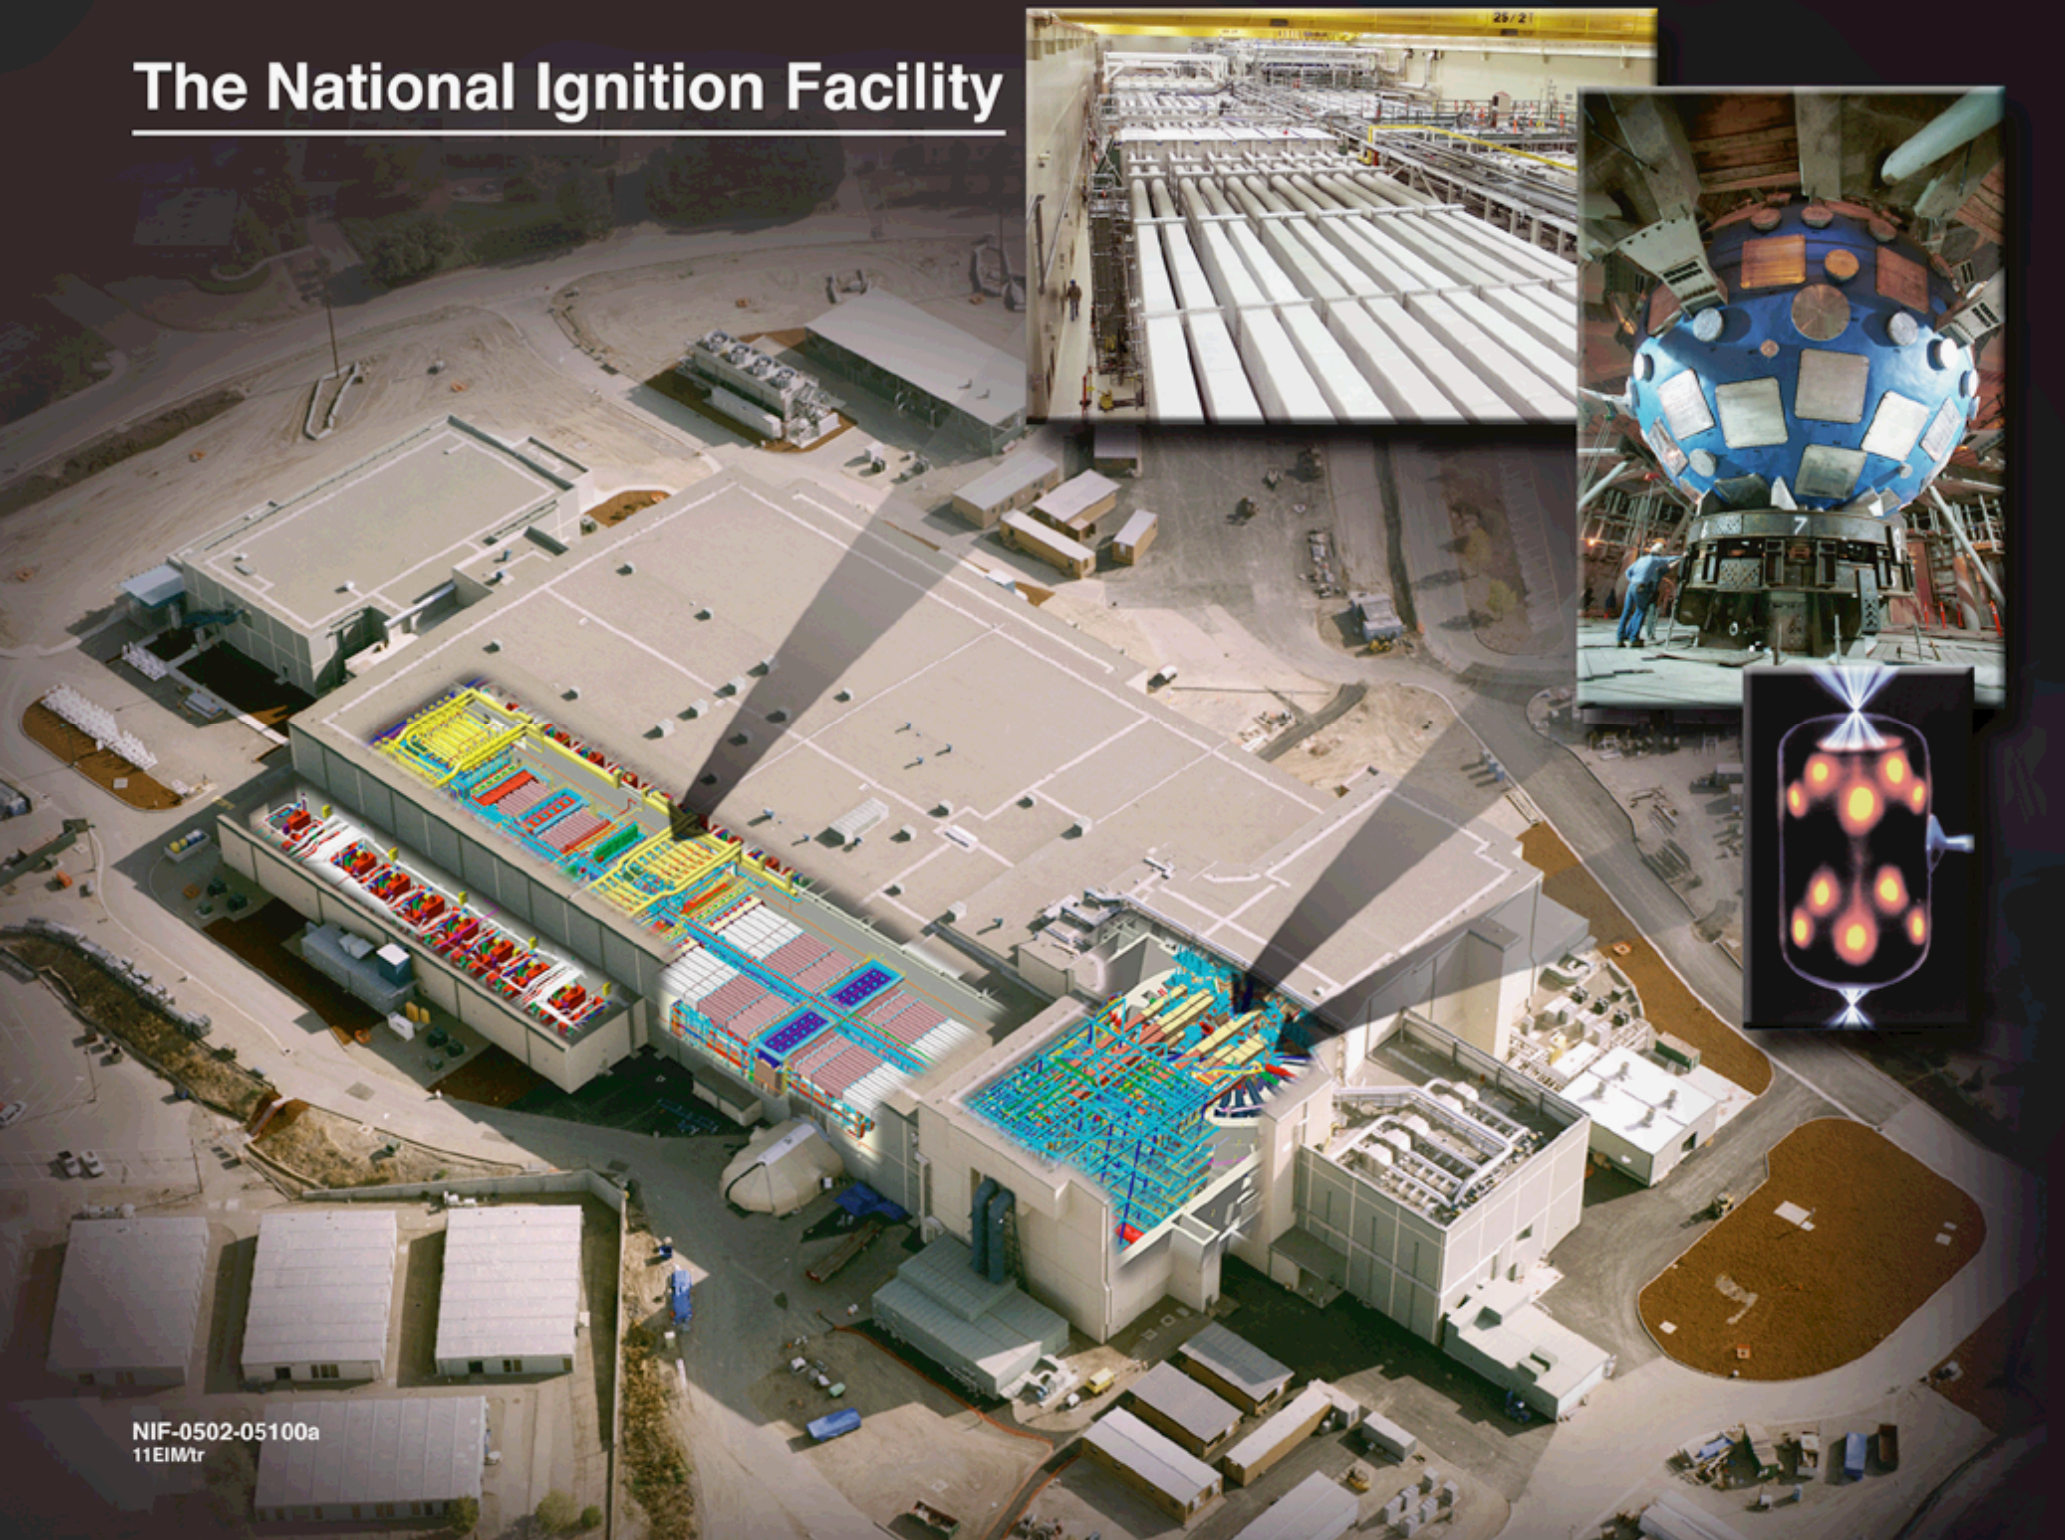

---

*The National Ignition Facility*

- **Partially missing**
- **Blobs may be divided into two**
- **Successive approximation may fail if initial guess is incorrect**
  - **automated guess correction by counting the right and wrong moves**
